

A Counter Example of Invariant Deformation Quantization

Xiang Tang

February 1, 2008

Abstract

In this note, we will show one example of hamiltonian Lie algebra action which has no invariant star product.

1 Introduction

Quantization of a hamiltonian system with symmetries is an important and difficult problem in physics and mathematics. In the deformation quantization formulation [4], this problem can be phrased as follows: given a hamiltonian Lie group action on a symplectic manifold, does there exist a star product containing (see Definition 1.3) the information of the group action?

Since the very early time of deformation quantization, Lichnerowicz has considered this question (see [17] and references therein). Lichnerowicz in [16] showed that if a homogeneous space G/H admits an invariant linear connection, the symplectic manifold $T^*(G/H)$ admits an invariant Vey $\star$ -product.

In literature, there are various definitions of a star product. We fix our star product to the following one.

Definition 1.1. *Let (M, ω) be a symplectic manifold. A star product on $C^\infty(M)$ is an associative product $\star$ on $C^\infty(M)[[\hbar]]$ with the following properties:*

1. *the coefficients $c_k(x)$ of the product*

$$c(x, \hbar) = a(x, \hbar) \star b(x, \hbar) = \sum_{k=0}^{\infty} \hbar^k c_k(x)$$

depend on a_i, b_j and their derivatives $\partial^\alpha a_i, \partial^\beta b_j$.

2. *the leading term $c_0(x)$ is equal to the usual commutative product of functions $a_0(x)b_0(x)$.*

3. *the $\star$ -product satisfies*

$$[a, b] = a \star b - b \star a = -i\{a_0, b_0\} + \cdots,$$

where $\{, \}$ means the Poisson bracket of functions and dots mean higher order terms of $\hbar$.

In this note, we will write a star product as $f \star g = \sum_{r=0}^{\infty} \hbar^r C^r(f, g)$, where C^r is a local bidifferential operator. Next we recall the definition of a Vey $\star$ -product.

Definition 1.2. *Let ∇ be a symplectic connection on (M, ω) . A $\star$ product is called a Vey $\star^n$ -product if the principal symbol of the differential operator C^r is identical to*

$$P_{\nabla}^r(f, g) = \omega^{i_1 j_1} \cdots \omega^{i_r j_r} \nabla_{i_1} \cdots \nabla_{i_r} f \nabla_{j_1} \cdots \nabla_{j_r} g, \quad \text{for all } f, g \in C^\infty(M),$$

for all $r \leq n$.

At the beginning of this section, when describing the question of quantization with symmetries, we have been very vague by using the word “containing”. In literatures, there are several related notions of invariant and covariant star products. In this paper, we will focus on the following invariant star product from [2].

Definition 1.3. *For a hamiltonian Lie group G action on a symplectic manifold (M, ω) , a $\star$ product is called strongly G invariant* if:*

$$x \cdot (f \star g) = (x \cdot f) \star (x \cdot g), \quad \text{for all } x \in G, f, g \in C^\infty(M).$$

Looking at the infinitesimal Lie algebra $\mathfrak{g}$ action and $J : \mathfrak{g} \rightarrow C^\infty(M)$ the dual of the momentum map, we have

$$\{J(X), f \star g\} = \{J(X), f\} \star g + f \star \{J(X), g\},$$

for all X in $\mathfrak{g}$, f, g in $C^\infty(M)$.

From Definition 1.2 and 1.3, we can easily see that if a Vey²-product is G -invariant, then the corresponding symplectic connection is also G -invariant. Therefore, Lichnerowicz’s result is also necessary for the existence of an invariant Vey²-product. A G -invariant Vey²-product exists if and only there is an invariant symplectic connection.

In Fedosov’s construction [12] of star products on a symplectic manifold, it is obvious that the existence of an invariant connection implies the existence of an invariant symplectic connection and therefore the existence of an invariant star product. With this and the integration trick, for any hamiltonian compact Lie group action, we can construct an invariant connection and therefore an invariant star product.

The existence of invariant star products leads to the study of quantum momentum map and reduction theory. Xu in [19] introduced and studied the theory of quantum momentum map. In [11] and [13], Fedosov used his quantization method to study quantum Marsden-Weinstein reduction of a compact hamiltonian Lie group action. Bordemann, Herbig, and Waldmann in [5] studied BRST cohomology in the framework of deformation quantization and quantum reduced space.

Recently, in literature, there are many attempts to extend the study of invariant star products and Xu’s quantum momentum map to more general types of quantization. In [18], Müller-Bahns and Neumaier considered star products of wick type; and in [14], Gutt and Rawsly investigated natural star products. All the known results have suggested that the original idea of Lichnerowicz that the existence of an invariant star product is closely related to the existence of an invariant connection is correct.

In the above discussion, we have concentrated on symplectic manifolds. It is worth mentioning the Poisson version of the question. The existence of a star product for a general Poisson manifold was first constructed by Kontsevich (and later Tarmarkin with a different method) in [15] using his formality theorem. From Kontsevich’s original construction, it is not very obvious to see the conditions needed for the existence of an invariant star product. Dolgushev in [9] gave an alternative construction of the global formality theorem using Fedosov type resolution and Kontsevich’s local formality theorem. Dolgushev’s construction explicitly shows that the existence of an invariant connection is a sufficient condition for an invariant star product (also invariant formality theorem). It would be interesting to look at the Poisson version of quantum momentum maps and BRST quotients.

It is also worth mentioning that since [7] and [10], there has been discussion of conformally invariant symbol calculus and star products. These products are different from the star product defined in Definition 1.1 that they are highly nonlocal. The study of conformally invariant quantization is still at its early stage, and we even do not know whether a conformally invariant quantization always exists. However, we have seen its interesting relations to other areas of mathematics. For example, Cohen, Manin, and Zagier in [7] obtained this type of products from considering deformation of

*In short, we will just say “ G invariant” star product in this note.

modular forms. In [3], we will use this type of star products (also Fedosov's construction) to reconstruct Connes and Moscovici's universal deformation formula [8] of the Hopf algebra associated to codimensional one foliation.

In this note, we will show that there is a hamiltonian Lie algebra action which has no invariant star product, which can be viewed as an analog of Van Hove's "no-go" theorem in invariant deformation quantization.

In this direction, Arnal, Cortet, Molin, and Pinczon in [2] showed that on some coadjoint orbit $\mathcal{O}$ of a nilpotent Lie algebra $\mathfrak{g}$, there is no $\mathfrak{g}$ -invariant Vey²-product by showing that there is no invariant $\mathfrak{g}$ -connection.

What we will do is basically to extend their result to any star product. Since we are working in full generality, to show that there is no invariant connection as in [2] is not enough any more. We will study properties of general invariant differential operators, which will give us enough information to show the nonexistence of an invariant star product.

Remark 1.4. *This type of counter examples is at least believed to exist among experts we have talked to. But we cannot find any explicit example in literatures. If there is any other examples, please let us know.*

Remark 1.5. *On a large class of coadjoint orbits, invariant star products were constructed in [1] and references therein.*

Remark 1.6. *Weaker than invariant star products, people have introduced a notion of "covariant star products" (see [2]). Instead of the keeping the same action, we allow higher order modification to the group (Lie algebra) action. The existence and uniqueness of covariant star products are related to the lower order Lie algebra (Lie group) cohomology (see [18]). This year there are many interesting activities in this direction. This spring, Kontsevich conjectured that the automorphism group of the Poisson algebra of polynomial functions on R^{2n} is naturally isomorphic to the automorphism group of the corresponding $2n$ -dimensional Weyl algebra. And this summer in IHP, Gorokhovsky, Nest, and Tsygan showed the author a very interesting construction of their "stacky star product".*

Acknowledgement: The result of this paper was completed during my Ph. D. study in UC Berkeley. Firstly, I would like to thank my thesis advisor Alan Weinstein for proposing this question to me and many helpful comments and suggestions. I also want to thank Simone Gutt for answering me many questions in emails, and Gorokhovsky, Nest, and Tsygan for interesting discussion.

2 Main result

We look at $(\mathbb{R}^2, dx \wedge dy)$ with the Lie algebra $\mathfrak{g}$ action formed by the Hamiltonian vector fields generated by

$$x^3, x^2, x, y, 1.$$

$\mathfrak{g}$ is a 5-dim nilpotent Lie algebra[†]. By the expression of a star product, we can easily see that if a $\star$ -product is invariant under $\mathfrak{g}$ action, then each C^r of $\star$ has to be $\mathfrak{g}$ invariant, i.e.

$$X(C^r(u, v)) = C^r(X(u), v) + C^r(u, X(v)) \quad \forall X \in \mathfrak{g}, \quad u, v \in C^\infty(M), \quad r = 1, 2, 3, \dots$$

Therefore, in the following, we will first look at properties of differential operators that are invariant under the $\mathfrak{g}$ action. Then we will come back to the existence of an invariant $\star$ product.

We write a bidifferential operator as

$$C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l,$$

where we have used the Einstein summation convention.

[†]We can look at the Lie algebra of the corresponding hamiltonian vector fields, which has no center.

Property 2.1. *If a bidifferential operator $C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l$ is invariant under the $\mathfrak{g}$ action, then $C_{ij;kl}$ satisfies the following relations:*

1. $C_{ij;kl}$ are all constants.

2. if $i > l$ or $j < k$, then $C_{ij;kl} = 0$;

3.

$$\begin{aligned} C_{ij;kl} &= -C_{i+1,j-1;k-1,l+1}, & \text{for } j \geq 1, k \geq 1; \\ C_{ij;kl} &= -C_{i-1,j+1;k+1,l-1}, & \text{for } i \geq 1, l \geq 1. \end{aligned}$$

4.

$$\begin{aligned} C_{ij;kl} &= -C_{i+2,j-1;k-2,l+1}, & \text{for } j \geq 1, k \geq 2; \\ C_{ij;kl} &= -C_{i-2,j+1;k+2,l-1}, & \text{for } i \geq 2, l \geq 1. \end{aligned}$$

Proof. We work on each generator of $\mathfrak{g}$.

1. $1 \in \mathfrak{g}$. This part is trivial. Because the hamiltonian vector field of 1 is 0, every bidifferential operator is invariant under it.

2. $x \in \mathfrak{g}$. The hamiltonian vector field generated by x is ∂_y . If $C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l$ is invariant under ∂_y , then

$$\begin{aligned} \partial_y(C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l) &= C_{ij;kl}(\partial_x)^i(\partial_y)^{j+1} \otimes (\partial_x)^k(\partial_y)^l \\ &\quad + C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^{l+1}. \end{aligned}$$

We expand the left hand side of the above equation, and after cancellations, we have

$$\partial_y(C_{ij;kl}) = 0.$$

3. $y \in \mathfrak{g}$. Similar to the case of x , we get

$$\partial_x(C_{ij;kl}) = 0.$$

From the above, we have $\partial_x(C_{ij;kl}) = \partial_y(C_{ij;kl}) = 0$ on $\mathbb{R}^2$. Therefore, $C_{ij;kl}$ is a constant.

4. $x^2 \in \mathfrak{g}$. The Hamiltonian vector field generated by x^2 is $2x\partial_y$. The invariance of $C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l$ under $2x\partial_y$ gives

$$\begin{aligned} 2x\partial_y(C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l) &= C_{ij;kl}(\partial_x)^i(\partial_y)^j(2x\partial_y) \otimes (\partial_x)^k(\partial_y)^l + \\ &\quad + C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l(2x\partial_y). \end{aligned} \tag{1}$$

Setting $x = 0$ in the above equation, we get

$$C_{ij;kl}(\partial_x)^{i-1}(\partial_y)^{j+1} \otimes (\partial_x)^k(\partial_y)^l + C_{ij;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^{k-1}(\partial_y)^{l+1} = 0, \tag{2}$$

where the first term exists when $i > 0$, and the second term exists when $k > 0$.

(a) We look at terms of the form $(\partial_x)^i \otimes (\partial_x)^k(\partial_y)^l$. It is easy to find that the first term of Equation (2) does not have this kind of term since its existence requires j to be greater than or equal to 1. From this, we have

$$C_{i0;kl} = 0 \quad \forall k > 0.$$

(b) Next, we look at terms of the form $(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k$. Arguments like those above show that

$$C_{ij;k0} = 0 \quad \forall i > 0.$$

(c) If $j > 0, l > 0$, by (1), we get

$$C_{i+1,j-1;kl}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l + C_{ij;k+1,l-1}(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l = 0.$$

This shows that

$$C_{i+1,j-1;kl} + C_{ij;k+1,l-1} = 0.$$

Therefore,

i. if $j > 0, k > 0$,

$$C_{ij;kl} = -C_{i+1,j-1;k-1,l+1};$$

ii. if $i > 0, l > 0$,

$$C_{ij;kl} = -C_{i-1,j+1;k+1,l-1}.$$

According to (a), and iteration using i. of (c), we get that if $j < k$, $C_{ij;kl} = 0$.

Similarly, by (b) and ii. of (c), we get that if $i > l$, then $C_{ij;kl} = 0$.

5. x^3 . The Hamiltonian vector field generated by x^3 is $3x^2\partial_y$.

As in the arguments for x^2 , we get that

(a) if $k > 1$, $C_{i0;kl} = 0$;

(b) if $i > 1$, $C_{ij;k0} = 0$;

(c) if $j \geq 1$ and $l \geq 1$,

$$C_{i+2,j-1;k,l} + C_{ij;k+2,l-1} = 0.$$

We can rewrite it as the following,

i. if $j \geq 1$ and $k \geq 2$,

$$C_{ij;kl} = -C_{i+2,j-1;k-2,l+1};$$

ii. if $i \geq 2$ and $l \geq 1$,

$$C_{ij;kl} = -C_{i-2,j+1;k+2,l-1}. \quad \square$$

With above preparation, we prove the following theorem.

Theorem 2.2. *For the Hamiltonian $\mathfrak{g}$ action on $(\mathbb{R}^2, dx \wedge dy)$, there is no geometrically $\mathfrak{g}$ invariant $\star$ product.*

Proof. We prove the theorem by contradiction. Assume that there is a $\star$ product of $(\mathbb{R}^2, dx \wedge dy)$ of the form

$$\sum_{r \geq 0} \hbar^r C^r,$$

which is geometrically $\mathfrak{g}$ invariant.

For each $r > 0$, by the assumption of locality, we can write

$$C^r = C_{ij;kl}^r(\partial_x)^i(\partial_y)^j \otimes (\partial_x)^k(\partial_y)^l.$$

According to the associativity of $\star$ for the $\hbar^2$ -term and comparing the corresponding coefficients, we have that for any $f, g, h \in C^\infty(M)$,

$$C^2(fg, h) + C^1(C^1(f, g), h) + C^2(f, g)h = C^2(f, gh) + C^1(f, C^1(g, h)) + fC^2(g, h). \quad (3)$$

1. We look at the coefficient of the term $f_{yy}g_xh_x$.

- On the left hand side of equation (3).

- (a) $C^2(fg, h)$. It can possibly contribute the term $C_{12;10}^2$. But according to the conclusion of Proposition 2.1 that if $i > l$, then $C_{ij;kl} = 0$, we have $C_{12;10}^2 = 0$. Therefore, $C^2(fg, h)$ has no term of the form $f_{yy}g_xh_x$.
- (b) $C^1(C^1(f, g), h)$. There are two C^1 . As we have h_x term, the outside C^1 has to be of the form $C_{ij;10}^1$. According the result of Proposition 2.1, that if $i > l$, then $C_{ij;kl} = 0$, we have that there are only two possibilities for the outside C^1 :

$$C_{01;10}^1 \quad \text{and} \quad C_{02;10}^1.$$

If the outside C^1 contributes $C_{01;10}^1$, then as all the $C_{ij;kl}^1$ are constant, the inside one also has to contribute $C_{01;10}^1$. Therefore, there is a contribution of $(C_{01;10}^1)^2$.

If the outside C^1 has $C_{02;10}^1$, then the inside C^1 can only contribute $C_{00;10}^1$, but from Proposition 2.1, it has to be 0, because $j < k$.

So the second term has only one contribution which is $(C_{01;10}^1)^2$.

- (c) $C^2(f, g)h$. Because in this term there is no derivative respect to h , this term can not contribute anything.

In summary, the left hand side of the above equation can only contribute $(C_{01;10}^1)^2$ to the coefficient of $f_{yy}g_xh_x$.

- On the right hand side of equation (3).

- (a) $C^2(f, gh)$. It can only possibly contribute $C_{02;20}^2$. But according to Proposition 2.1,

$$C_{02;20}^2 = -C_{21;01}^2.$$

But from $i > l$, we know $C_{21;01}^2 = 0$. Therefore, there is no contribution of this term.

- (b) $C^1(f, C^1(g, h))$. By comparing the number derivatives of f , we know that the outside C^1 has to be of the form $C_{02;kl}^1$. As the differential of g and h are all respect to x , there are three possibility for the outside C^1 .

$$C_{02;00}^1, \quad C_{02;10}^1, \quad \text{and} \quad C_{02;20}^1.$$

In the following, we will show that all three of them do not have any contribution.

- i. $C_{02;00}^2$. Then the inside C^1 has to be of the form $C_{10;10}^1$. This is 0 according to Proposition 2.1.
- ii. $C_{02;10}^2$. Then the inside C^1 has to be of the form $C_{10;00}^1$ or $C_{00;10}^1$, which are both 0 because of Proposition 2.1.
- iii. $C_{02;20}^2$. From the previous calculation, we know that $C_{02;20}^2 = 0$.
- (c) $fC^2(g, h)$. Because this term has no derivative of f , there is no contribution of this term.

In all, total in both sides of equation (3), there is only one contribution of the term $f_{yy}g_xh_x$, which is $(C_{01;01}^1)^2$. Therefore, we have

$$C_{01;10}^1 = 0.$$

2. We look at the coefficient of $f_{xx}g_yh_y$.

- On the left hand side of equation (3).

- (a) $C^2(fg, h)$. The only possible contribution is $C_{21;01}^2$. But according to Proposition 2.1, $C_{21;01}^2 = 0$.
- (b) $C^1(C^1(f, g), h)$. By comparing the derivatives of h , we get that the outside C^1 has to be of the form $C_{ij;01}^1$. As i has to be less than or equal to 1, otherwise this term is 0 according to proposition 2.1, we know that there are four possibilities;

$$C_{10;01}^1, \quad C_{11;01}^1, \quad C_{01;01}^1, \quad \text{and} \quad C_{00;01}^1.$$

In the following, we will show that except for $C_{10;01}^1$, the other three cases have no contributions.

- i. $C_{10;01}^1$. In this case, the inside C^1 also has to be of the form $C_{10;01}^1$. The contribution of this term is $(C_{10;01}^1)^2$.
- ii. $C_{11;01}^1$. Then the inside C^1 has to be of the form $C_{10;00}^1$, but this has to be 0 because $i > l$. So this term has no contribution.
- iii. $C_{01;01}^1$. Then the inside C^1 has to be of the form $C_{20;00}^1$. This also has to be 0, because $i > l$. This term again has no contribution.
- iv. $C_{00;01}^1$. Then the inside C^1 has to be of the form $C_{20;01}^1$. This is 0 for the same reason as the $C_{20;00}^1$.
- (c) $C^2(f, g)h$. This has no contribution, because there is no derivative on h .
- On the right hand side of the relation.
 - (a) $C^2(f, gh)$. The only possible contribution of $C^2(f, gh)$ is of the form $C_{20;02}^2$. This has to be 0, because $C_{20;02}^2 = C_{01;21}^2 = 0$.
 - (b) $C^1(f, C^1(g, h))$. Comparing the part of f , we know that the outside C^1 has to be of the form $C_{20;kl}^1$. As i has to be less than or equal to l , the outside C^2 has to be of the form $C_{20;02}^2$, which is 0.

In conclusion, total in both sides of equation (3), there is only one contribution $(C_{10;01}^1)^2$ for term $f_{xx}g_yh_y$. Therefore $C_{10;01}^1 = 0$.

We have shown that $C_{10;01}^1$ and $C_{01;10}^1$ are both 0. But on the other hand, from

$$[u, v] = u \star v - v \star u = -i\hbar\{u, v\} + o(\hbar),$$

we have

$$C_{10;01}^1 - C_{01;10}^1 = -i.$$

If $C_{10;01}^1 = C_{01;10}^1 = 0$, the above equality can not be true. So we get a contradiction. Therefore, there is no geometrically $\mathfrak{g}$ invariant star product on $(\mathbb{R}^2, dx \wedge dy)$. $\square$
